A Message from Genesis

The transparency, detail retrieval, macro- and micro-dynamics, and wide frequency extension of Genesis loudspeakers place great demands on the quality of amplification. Hence, to match the Genesis loudspeakers, the Genesis Reference Series of amplifiers was created as the finest amplifiers available for music reproduction in the home.

The Genesis Reference Amplifier, together with a pair of Genesis loudspeakers, will give your entire music collection a whole new life. In a well set-up system, it is capable of transporting the musical performance into your room. The hiss and hum normally associated with vacuum tubes are completely absent, while retaining the richness and rightness of the best of this genre of amplifiers. Transistor etch and harshness are completely absent, while retaining the slam and control of the best of solid-state.

During development, we benchmarked against the best cost-no-object amplifiers – both solid-state and vacuum tube. While we were intent on developing a value-priced product, quality has not been scaled down. Hand-selected, precisely matched components are used throughout: silver wires with Teflon insulation and a copper core are used in the entire signal and power path. Each and every unit is completely hand-assembled in the USA, and burned-in before final testing and measurement.

The result of all this obsessive attention to detail is a fabulously musical power amplifier capable of driving almost any loudspeaker in the world. The state of the environment is also taken care of with extremely high efficiency, instant warm up, and a simple, functional, and elegant design.¹

Before using this unit, please take the time to carefully review the safety instructions and operating information contained in this Owner’s Manual. Becoming familiar with your new amplifier and the correct operating procedures will help assure you of safe usage, reliable operation, and maximum musical enjoyment.

Please write the serial number and purchase details of your Genesis Reference Amplifier here for future reference.

Date: _____

Address: _____

Tel: _____

¹ Some of the inspiration for the GR-Amp came from the sci-fi movies “Silent Running” and “Max Headroom: 20 Minutes into the Future”.

Set-up and Safety Information

Now that you have your new amplifier, we realize that you can't wait to hook it up and start playing! However, please read this set-up guide and safety information before you proceed.

Unpacking and Setting Up

The amplifier is likely to come in parts – the amplifier module, an acoustic suspension, and a power transformer (an additional power supply upgrade called the Maximum Dynamic Headroom Reservoir is also available) unless your dealer has assembled it for you. So, some assembly may be needed before you can start playing. It is important that this product is never used near water or sources of water. Avoid bathrooms, washbowls, kitchen sinks, swimming pools, etc.

Carefully remove the various parts of the amplifier package from the cartons and unwrap it. The suspension system will need to be assembled to the amplifier chassis. You will use the hex key and four hex screws supplied to do this.

Place the amplifier chassis top down on a clean surface. Place the suspension frame on the shock absorbers so that the holes of the shock absorbers are aligned with the matching holes on the frame. The suspension frame “points” forwards so that the tip of the triangle faces to the front of the amplifier, and the round hole is in the front.

Use the hex screws and the supplied hex key to secure the suspension frame to the shock absorbers. Do not over-tighten the screws.

Turn the amplifier over, screw in the steel spike bolts into the threaded holes in each corner of the suspension frame. Screw them in so that the spikes protrude by about a third of an inch (8mm) from the bottom of the frame and no more.

The Acoustic Suspension will allow the amplifier to be placed directly on the floor, or on any piece of furniture or equipment rack. The amplifier should not be subject to vibration of any sort. Do not place them directly in front of, or on top of your loudspeakers. Despite the vibration and resonance control measures already taken in the Genesis Reference Amplifier, we are not able to completely eliminate all incoming vibration.

Once you decide on the placement of the amplifier module, connect everything up before you plug the power transformer into the wall. Connect the amplifier module to the power transformer using the supplied Power Umbilical; locate the power transformer module as far away as possible from the amplifier module and other electronics. The Power Umbilical will only go in one way so the assembly should be obvious. Align the plugs to the like-colored sockets, insert and twist until the lock “clicks”.

Please note that the Neutrik PowerCon connectors used for the Power Umbilicals are designed for passing current, and not for making/breaking current. Hence, ***always unplug the Power Transformer from the wall outlet before connecting/disconnecting the PowerCon connectors.***

If you have the optional Maximum Dynamic Headroom Reservoir (MDHR), place that on top of the amplifier module², and connect the two modules using the short Power Umbilical supplied with the MDHR. Then, connect the power transformer module to the MDHR.

Before you plug the power cord in the power transformer, please make sure that you have the power transformer with the proper voltage for the country you are in. Taiwan, Japan and North America will require the 115V version. Most European countries and other Asian countries will require the 230V version. Also, make sure that you have the appropriate power transformer for the amplifier model that you have. There is also a version of the Power Transformer for the GR180 and a different version for the GR360/ Monoblocks. If you own both the GR180 and the GR360, please do not mix the two up.

Connect the loudspeakers to the 5-way binding posts using good quality loudspeaker cables. Do not over tighten the speaker connectors. They are designed to be finger tightened only (not with tools). Using the appropriate RCA or XLR interconnect, connect to the pre-amplifier. If you have the Reference Monoblocks or the Statement amplifier, it will have both RCA and XLR inputs. In this case, flick the switch towards the input being used – RCA or XLR. *Do not connect both RCA and XLR inputs at the same time.*

² Note that the rubber feet of the MDHR *may* mark the top of the amplifier module, but this is easily cleaned off using rubbing alcohol or “Goof Off”. However, please note that the placement and material of the rubber feet will serve to further damp the top plate of the amplifier module. Do not be tempted to use cones or other forms of isolation between the MDHR and the amplifier module. The top of the amplifier chassis holds the signal path.

Safety Information

1. Never try to disassemble the amplifier as you may be exposed to dangerous voltages. Even after turning the amplifier off and unplugging it from the wall socket, it will retain a lethal electrical charge for a very long time. There is huge energy storage in the power supply capacitors (and even more so in the MDHR!).
2. Do not attempt to modify the amplifier. The device has been tested and adjusted for optimal operation and should give you years of trouble-free service.
3. Do not connect/disconnect the power supply and power transformer from the amplifier module without turning the amplifier off and unplugging the power transformer from the wall outlet first.
4. Before turning the amplifier on, both inputs and outputs should be properly connected. Do not run the amplifier without appropriate loudspeakers connected to it.
5. While the Genesis Reference Amplifier runs very cool due to its high efficiency, some ventilation and airflow is necessary for reliable operation. Do not obstruct the vents at the sides of the chassis, or the holes on the bottom cover.
6. Do not connect or disconnect the inputs to the amplifier while it is playing – you may damage your loudspeakers. Turn the preamplifier and power amplifier off, wait a few seconds, then make/break any connections.
7. Do not connect or disconnect the loudspeakers from the amplifier while it is playing. Turn the amplifier off, and wait a few seconds before making any connections.
8. In general, a hifi system should be turned ON starting at the source components towards the power amplifier, and turned OFF starting at the power amplifier towards the source components. This is so that just in case there is any turn on/turn off electrical instability, it will not damage your system.

Set-up and Operation

Speaker Connections

Two pairs of 5-way insulated binding posts are provided on the rear of your amplifier (One pair for a monoblock). While they allow bare wire to be used, we recommend that firstly spades, or secondly bananas be used instead of bare wire. Make sure that your speaker cables are firmly connected to the correct speaker connections.

The binding posts are ETI CablePods™ for improved signal transfer, enhanced sonic performance, and a faster, more direct connection. The positive (signal) terminal is identified by the red ring on the base; and the negative (return) terminal is identified by the black ring on the base.

If you are using banana plugs, you may have to remove the little black plastic covers (if installed) on the end of each CablePod™. If you are using spade lugs, unscrew the binding posts, insert the spades, and hand tighten. Do not use pliers or other tools to tighten the binding posts as you may strip the plastic threads on the posts. These ETI CablePods are designed to fully tighten without the use of tools.

DO NOT SHORT THE TERMINALS TOGETHER AND DO NOT GROUND THE LOUDSPEAKER TERMINALS

Unlike many other Class D amplifiers, the output terminals of the GR-Amp do not “float” at a significant voltage above ground potential – which makes the GR-Amp useable with all loudspeakers, including those with built-in powered subwoofers and electrostatic designs. However, this does NOT mean that you can ground the negative terminal of the speaker outputs. Do **NOT** short the two negative (return) terminals together.

Input Connections

Use a pair of high-quality interconnects to hook up the output of your preamplifier to the input of the GR-Amp. The balanced-input GR-Amp is a fully balanced, differential amplifier, and hence, a true-balanced source is crucial for top performance.

The balanced input of the GR-Amp uses the standard configuration for the XLR input of pin 2 “hot” or +ve. Pin 1 is signal ground, and pin 3 is the signal

-ve. The Genesis Reference Amplifier preserves phase, hence if the input XLR pin 2 is positive, the speaker output red binding post will be positive.

The use of single-ended to balanced converters that simply short pin 3 to ground is not recommended as performance will be severely compromised. Some form of balancing adapter may be used, but the performance of the GR-Amp will be limited by the sonic quality of the device. A high quality transformer-based single-ended to balanced converters can be used between your single-ended preamplifier and the GR-Amp.

The single-ended version of the GR-Amp converts a single-ended input into the balanced signal required by the amplifier at a very slight reduction in transparency. The single-ended version of the GR-Amp is ground-lifted. Hence, more care may be needed in the grounding scheme of your entire system.

With the Monoblock and Statement GR-Amp, both single-ended and balanced inputs are provided. A switch above the inputs selects RCA or XLR input. However, in the interest of not putting any more circuitry than is absolute necessary, the balanced XLR input is always “live” even when RCA is selected. Hence, do not connect both inputs at the same time.

Playing Music

Make sure that your amplifier is properly connected to a high-current power outlet through the Power Transformer. Before you turn the amplifier on, check that the speaker connections and inputs are properly hooked up and tightened. Make sure that you turn down the volume control on your preamplifier or place it in mute first.

Locate the power toggle switch on the back next to the power umbilical inlet and **flick it upwards** to turn the amplifier ON.

Alternatively, you may have a lockable socket that will accommodate a 12V trigger from a home theater system or other switching system that will remotely turn your amplifier on.

In less than a second, you will hear a faint click to indicate that the soft-start circuit has engaged and the LED(s)³ under the amplifier will glow.

³ Note that there are two blue LEDs under the 360W stereo amplifier module, and one blue LED under the 360W monoblock amplifier and 180W stereo amplifier module.

Unlike most power amplifiers, the power toggle switch on the back of the amplifier is not the actual power switch. We have found that most toggle or rocker switches degrade the power supply path. Hence, the power switch is a low-voltage, low-power trigger that switches in a pair of high-current hermetically sealed relays with silver contacts that is the actual power switch.

Flicking the switch up energizes a low-power circuit that then trips the two high-current relays that turn the power amplifier on, and a split second later, unmutes the amplifier.

Give your amplifier a warm-up period of at least 10 seconds for the circuits to stabilize before attempting to play any music. Because of special “stay warm” circuitry, as long as the amplifier is plugged in continuously, it will warm up almost instantly*, and be ready to play the moment you turn it on. The “stay warm” circuits consume about as much power as a night-light (6W), and even when powered on and playing music, the Genesis Reference Amplifier consumes less than 25W during continuous play.

To turn the amplifier back to stand-by, flick the power switch down. When you know that you will not be using the amplifier for a long period of time (for example when you leave on a business trip or a vacation), please unplug the power transformer at the wall outlet.

* Why do we keep the amplifier on “standby” and hence “waste” electricity? We believe that it is preferable to turning on an amplifier that consumes 300W for an hour to warm up before listening. If you listen to music every day, and turn your conventional power amplifier on for an hour before you start to listen, you waste at least 300W before every listening session. Leaving the Genesis amplifier on for 2 days consumes about the same amount of electricity. Leaving the unit on stand-by also extends the life of the power supply, hence reducing waste in throwing away expensive, valuable components.

About Your Amplifier

Background

The Genesis Reference Amplifier uses proprietary designs and circuits, high quality components, and state-of-the-art Class D amplifier modules to deliver sonic performance rivaling amplifiers costing much, much more. The design brief was to deliver a load-invariant, wide-bandwidth amplifier that would deliver the musicality, emotion, and tonal colors of a low-powered valve amplifier with the reliability, power, and control of a high power solid-state design.

A valve amplifier matched with an appropriate loudspeaker can produce a sound that we can only call magic. The hard, brittle, and edgy presentation of many transistor amplifiers is contrasted with the rich, lush and silky sound of the tube amplifier. Often, valve amplifiers offer much better imaging and sound stage presentation compared to an equivalently priced solid-state amplifier. It is more musical, and the performance seems almost *alive*.

However, a solid-state amplifier often offers better control and dynamics, is easier to set-up and to own (without having to change tubes every so often). Except for Class A solid state amplifiers, they also run much cooler and consume less electricity than valve amplifiers. Solid-state amplifiers are also able to drive a far wider range of loudspeakers than most valve amplifiers.

The Genesis Reference Amplifier (GR-Amp) offers the best of both worlds, without the disadvantages of either.

Design and Construction

The GR-Amp challenges the status quo of music amplifiers by marrying the advantages of tube (emotion, imaging, soundstage, and portrayal of tonal colors) with solid state (control, dynamics and accuracy). It uses a modified Class D power amplifier module with ground-breaking power supply technologies, and resonance and vibration control to achieve this.

Dynamic Power Delivery Supply (DPDS)

Traditional DC power supplies developed with established design principles are usually specified into a constant steady current draw with a resistive load. However, except for Class A amplifiers (and Class AB at low power), the load is not linear. The power supply is hence specified for the maximum current drawn, but such a huge power supply is often slow. Resulting in a dark, brooding, muscle-bound sound.

The Genesis DPDS, on the other hand, is designed to deliver current into a non-linear, dynamic, rapidly changing musical load, leading to a sense of

power with finesse. The result is that the Genesis Reference Amplifier has the dynamics, extension and drive of high-power transistor amplifiers without the muscle-bound sound, and the elegance, emotion and tonal colors of flea-powered single-ended triode vacuum tube amplifiers without being weak or flaccid.

The origins of the DPDS comes from the principles of tube amplifier design – some of the qualities of tube amplifiers were as much to do with power supply design as the choice of tubes over transistors. Because of the high voltages involved, tube amplifiers use relatively small capacitors and chokes to produce smooth DC power.

Transistor amps use cheaper, larger, and lower-voltage electrolytic capacitors to do much the same job. From this we discover a very simple fact, smaller capacitors usually sound better. This is not only speculation, there is good science to predict that the high frequency performance of large capacitors to be poor. The time-constant, or speed at which a capacitor can deliver its charge is determined by the capacitance (or size) of the capacitor. The larger the capacitor, the slower it is.

There are lots of very small solid-state amplifiers that have excellent sound. They all have tiny power supplies, and the smaller the power supply, the “faster” they sounded. On the other hand, very large power amplifiers with huge capacitors, or even large banks of smaller capacitors in their power supplies tended to sound dark and slow.

The DPDS in the simplest explanation uses the frequency distribution of music, and the Fletcher Munson curves to predict the required power delivery to play back music. Then, it uses a Class D amplifier module as a “perfect music-driven faucet” to switch current to the connected loudspeakers.

This is the issue of speed vs power. The sprinter is not able to sustain the delivery of power for very long, but the marathon runner is not able to deliver very quick bursts of speed. The DPDS is like a relay team with sprinters, medium-distance, and long distance runners in the team. Thus, it is able to deliver high power, as well as very quick bursts of speed.

Such a “relay team” is what gives the Genesis Reference Amplifier the excellent micro-dynamics, tonal contrasts and timbre textures of low-powered amplifiers, and yet is able to deliver huge dynamics and the sustained deep bass of muscle amps.

The optional Maximum Dynamic Headroom Reservoir extends this ability down to loudspeaker impedances of 1 ohm and below by extending the relay

team, and adds proprietary resonance control circuitry to ensure that the “baton handover” from one team member to the next is handled as smoothly as possible. This results in increased dynamics from having more current available into lower impedance loads and better micro-dynamics – one listener described it as “having cream in your coffee instead of non-fat soy”.

Silent Running Voltage Supply⁴

We recognized that published specifications for noise rejection of opamps and even discrete small-signal amplification circuits did not always tell the whole story. The problem is that Power Supply Rejection Ratio, or PSRR, is specified at one frequency – usually 1kHz, but the truth is that this rapidly gets worse as the frequency rises. This is likely to have given rise to the often heard audiophile statement that “opamps sound grainy”.

For the GR-Amp, a new low-current regulated voltage supply was developed that has broad bandwidth noise rejection so that incoming noise does not intrude on your music.

Audio Band Noise Rejection (over –90dB flat all the way up to 40kHz)

The electronics used for regulation have to be noiseless and fast. Generally noiseless is not a problem but fast is a great problem. Most commercial regulators are good for about 100 kHz. Most chokes are good for at least 1 MHz.

The electronic regulator used in the GR-Amp exceeds the specifications of an excellent choke. It is an exceedingly fast discrete circuit and not a generic design. Spectrum

analysis up to 16 MHz implies a very high bandwidth, as there is no apparent degradation at that frequency. The circuit is of low enough impedance to outperform commercial regulators by at least 10 dB. This is despite the fact that no loop feedback is used in this circuit. To avoid any speculation, it is not a shunt device, it is not a capacitive multiplier, and it does not employ chokes.

⁴ Genesis would like to credit Engr. Nigel Pearson for the design of the SRVS.

It will not surprise many to know that the avoidance of loop negative feedback is the key to this design. Having established a design, the components used were individually selected by extensive and laborious listening sessions. A discrete design allowed that as each component is hand picked to get the optimum result. Every component on the design was individually chosen, as was the grounding paths.

Resonance and Vibration Control

With all the emphasis on reducing noise from the power supply coming into the amplifier, it makes no sense if the amplifier itself creates vibration or generates radio frequency interference and electro-magnetic interference. Hence, one key feature of the GR-Amp is the outboard power transformer.

There is no way to eliminate hum and vibration from a large powerful transformer. This is because even for the best-built transformer, the incoming 50Hz or 60Hz in the coils will shake the steel in the transformer core. Moreover, if the incoming power is not a perfect sinusoidal waveform, the transformer will rattle and buzz even more.

For example, a single switched mode power supply in the same electrical circuit as the transformer will cause asymmetric compression of the power waveform and induce noise into the power transformer. Moreover, noise-generating devices such as light dimmers, electric curling irons, microwave ovens, etc. can also cause the transformer to vibrate at those noise frequencies. Capacitive coupling between the primary and secondary windings of the transformer will result in high frequency noise bleeding through from the input to the output.

A phenomenon that we noted in the design of the transformer is that when the coils are wound so tightly that the transformer does not emit an audible hum, the transformer will vibrate and heat up even more. It is intuitive that the incoming sine wave needs to be dissipated in some way – in the form of sound, heat, or vibration.

With the transformer moved outside of the chassis, the Genesis Reference Amplifier has a much quieter environment in which to operate. To further reduce the vibration/resonance within the chassis, the signal and power circuits are isolated from each other. The signal circuits are softly “hung” using a neoprene “hammock” from the top cover of the chassis, while the power circuits are stiffly mounted on the bottom plate using plastic posts.

This choice of differently compliant mounting is because of the different susceptibility of the two different circuits to different frequencies of vibration and resonance.

Acoustic Suspension System

A dedicated suspension system completes the resonance and vibration control design of the Genesis Reference Amplifier. It also facilitates the easy placement and location of the amplifier.

Designed like the suspension system of a race car, the acoustic suspension is made of a solid acrylic suspension frame, neoprene shock absorbers, and steel spikes. It isolates the amplifier from floor- or structure-borne vibrations, and yet at the same time allows any vibration in the amplifier chassis to be “sunk” to ground.

The function of the steel spike is to have a low-impedance point to transfer all frequencies to ground. This is possible because the contact at the point of the spike is smaller than a $\frac{1}{2}$ wavelength of the frequencies of vibration transmitted. Using a steel cup under the spike will defeat this function and as this will only allow passing frequencies have a $\frac{1}{2}$ wavelength larger than the diameter of the steel cup, which is far larger than the point of the spike.

Hence, if the amplifier is to be placed on a hardwood floor, and you do not want to mark the floor, use a thin disc of copper (a copper penny will do) under each spike. The weight of the amplifier on the spike will deform the disc and create a small indentation. The other side of the indentation will form a little nipple to couple to the hardwood floor. Alternatively, use a little square of aluminum foil that is at least 4 layers thick.

Other features that have been incorporated include:

- A grounded Faraday Cage steel chassis for RFI and EMI rejection improves micro-dynamics, and tonal colors and contrast.
- All internal power and signal wiring using silver strands with a copper core and PTFE dielectric. The silver strands are wound so tightly together that the strands “imprint” on each other and combine to act almost as a solid-core wire. Thus, the internal wiring has the qualities of both solid-core as well as stranded wire.
- Having all critical components toleranced and matched to less than +/- 1% results in a sense of aliveness and ease in the music.
- Special circuitry to “keep things warm” without wasting a lot of electricity means that your system is ready for you to listen to whenever you are.
- High-power, high current relays to switch power instead of typical rocker or toggle switches result in minimal degradation of the power supply path.

Specifications (Each)

- Rated Power Output: 180w, 360w or 1440w per channel
(@ 4ohm)
Current limited to 20amps for 20ms
- Frequency Response: 10Hz ~ 50kHz +0dB/-3dB
- Power Bandwidth: 18Hz to 36kHz
- Input Impedance: 100k Ohms (Balanced or Single-ended)
- Damping: 2,000 minimum at 4 ohms
- Gain: 26dB
- Inputs: Balanced XLR and/or Single-ended RCA
- Output: ETI CablePods™ 5-way binding posts
